Abstract

Identity verification is a fundamental requirement in modern digital systems, particularly in domains such as banking, e-governance, border security, and corporate access control. Traditional verification methods rely heavily on manual inspection of identity documents, which are time-consuming, error-prone, and vulnerable to fraud and identity theft. With the increasing demand for secure and efficient verification systems, there is a need for automated solutions that can operate accurately under real-world conditions.This project presents ScanPoint: A Real-Time ID Detection System using Machine Learning, which integrates computer vision, Optical Character Recognition (OCR), database validation, and biometric face recognition into a unified framework. The system utilizes OpenCV-based preprocessing techniques, including grayscale conversion, denoising, thresholding, and morphological operations, to enhance image quality before text extraction.Tesseract OCR is employed to extract key textual information such as name, ID number, date of birth, and address from identity documents. The extracted data is further processed using regex-based parsing and error correction techniques to improve accuracy. A database validation module is incorporated to verify the authenticity of identification numbers by comparing them with stored records.

In addition to textual verification, the system implements a biometric verification module using a Siamese neural network based on the ResNet50 architecture. This module compares the facial image from the ID card with a live image of the user to ensure identity consistency. The integration of these components enables a multi-layered verification approach that enhances reliability and reduces the chances of fraud.Experimental results demonstrate that the system achieves high accuracy (approximately 95%) and performs efficiently in real-time scenarios. The proposed system offers a scalable and robust solution for applications such as KYC processes, fraud detection, secure access systems, and digital identity verification.

Chapter 1

Introduction

Modern identity verification systems are under increasing pressure due to the rapid growth of digital services, population expansion, and the rising demand for secure authentication mechanisms. In urban environments, where large volumes of users require verification in real-time such as in banking, transportation, corporate security, and e-governance the need for efficient and scalable identity verification systems has become critical.These challenges have led to the generation of large-scale visual and textual data in the form of identity documents captured through mobile devices, scanners, and surveillance systems. However, variations in lighting conditions, document quality, orientation, and background noise significantly affect the reliability of traditional verification methods .

Identity verification errors can be broadly categorized into system inefficiencies and fraudulent activities. System inefficiencies arise due to limitations in traditional rule-based and OCR-only approaches, which struggle to accurately extract and interpret textual information under real-world conditions [1]. On the other hand, fraudulent activities such as forged documents, identity theft, and impersonation pose serious security risks and financial losses across industries.In real-world scenarios, relying solely on textual verification is insufficient, as extracted data may

be manipulated or forged [2]. Similarly, standalone biometric systems may fail under conditions such as poor image quality, occlusions, or variations in facial expressions . Therefore, a robust identity verification system must integrate multiple layers of validation to ensure accuracy and reliability.Recent advancements in machine learning and computer vision have enabled the development of intelligent systems capable of handling complex verification tasks. Traditional methods such as rule-based OCR have evolved into deep learning-based approaches using Convolutional Neural Networks (CNNs) for feature extraction and Siamese Neural Networks (SNNs) for biometric face matching. These models are capable of learning complex patterns and performing similarity-based comparisons between images [3]. However, despite these advancements, a critical challenge remains the lack of fully integrated systems that combine OCR, biometric verification, and database validation into a unified real-time framework. Many existing solutions operate in isolation, limiting their effectiveness in detecting fraud and ensuring data authenticity .

This project presents ScanPoint: A Real-Time ID Detection System using Machine Learning**,** which proposes a multi-layered identity verification framework. The system integrates OCR-based text extraction, database-backed validation, and deep learning-based face recognition into a closed-loop pipeline [4] [5]. Textual information extracted from identity documents is validated against stored records, while biometric verification ensures consistency between the ID photo and the individual [6] [7].

1.1 Organisation of the paper

1. The primary focus of this project is to design and implement a machine learning-based identity verification system that integrates real-time ID detection, OCR-based text extraction, and biometric face recognition to address challenges faced in modern digital verification systems .
2. The report discusses the background and motivation behind the proposed system, highlighting the limitations of traditional manual verification methods and the increasing risk of identity fraud, document forgery, and impersonation in real-world scenarios.
3. An in-depth review of existing literature on OCR-based identity detection systems and face recognition techniques using deep learning models such as Convolutional Neural Networks (CNNs) and Siamese Neural Networks is presented, emphasizing their performance, limitations, and gaps in current approaches .

4. The study formulates the problem statement and presents a detailed system architecture describing the end-to-end workflow, including image preprocessing, text extraction, database validation, and biometric face matching.
5. The report presents experimental results and performance analysis, evaluating the effectiveness of the proposed system in terms of accuracy, processing time, and reliability under real-world conditions.
6. The study also discusses system limitations, identifies research gaps, suggests future enhancements such as improved deep learning models and real-time deployment strategies, and concludes with the overall contributions and practical applications of the proposed system.

1.2 Background Study

a. **Identity Verification Systems: Increasing Demand in Urban Environments**

In modern urban environments, identity verification systems play a crucial role across sectors such as banking, transportation, corporate security, and e-governance. With the rapid increase in digital services and online transactions, the need for fast, accurate, and secure identity verification has grown significantly. In densely populated regions, large volumes of identity checks are performed daily, creating a demand for systems that can operate efficiently in real-time.Unlike traditional systems that rely on manual inspection, modern environments require automated solutions capable of handling diverse inputs such as images captured through mobile devices, surveillance cameras, and scanners. Variations in lighting, document quality, and orientation introduce additional complexity, making it difficult for static or rule-based systems to perform reliably .

b. **Challenges in Traditional Identity Verification Systems**

Traditional identity verification methods are primarily based on manual inspection and rule-based validation. These approaches are time-consuming and prone to human error, especially when dealing with large volumes of data. Moreover, they lack consistency, as different operators may interpret documents differently. In real-world scenarios, identity documents often suffer from issues such as blur, noise, shadows, and partial occlusions. These factors significantly reduce the accuracy of conventional OCR systems. Additionally, manual verification systems are unable to detect subtle fraud techniques such as forged documents, manipulated text, or impersonation, leading to security vulnerabilities .

c. Identity Fraud as a Major Security Concern

Identity fraud has become a significant challenge in modern verification systems. Fraudulent activities such as fake ID creation, document tampering, and identity theft can result in financial losses and security breaches. One of the major issues is that traditional systems rely solely on textual data, which can be easily manipulated. Fraud also impacts system reliability in two major ways. First, incorrect or forged data leads to inaccurate verification results, reducing trust in the system. Second, the absence of biometric validation allows unauthorized individuals to use stolen or fake identity documents without detection. Existing systems often fail to identify such complex fraud patterns due to their limited capabilities .

d. Variability in Real-World Data and Environmental Conditions

Identity verification systems must operate under highly variable conditions. Factors such as lighting changes, camera quality, motion blur, and document orientation significantly affect system performance. Additionally, identity documents may vary in format, language, and layout, making it challenging for systems to generalize across different scenarios. Traditional approaches struggle to handle such variability, as they rely on predefined rules and fixed templates. Without adaptive learning mechanisms, these systems fail to respond effectively to real-time variations, resulting in reduced accuracy and reliability.

e. Artificial Intelligence as a Transformative Solution

Artificial intelligence (AI) provides a powerful alternative to traditional verification methods. Unlike rule-based systems, AI models learn from data and continuously improve their performance. Machine learning techniques enable systems to detect complex patterns in images and text, making them suitable for identity verification tasks. Optical Character Recognition (OCR) systems, combined with advanced preprocessing techniques, can extract textual information from identity documents with improved accuracy. Deep learning models such as Convolutional Neural Networks (CNNs) are used for feature extraction, while Siamese Neural Networks (SNNs) enable biometric face matching by comparing facial embeddings. The integration of OCR, biometric verification, and database validation creates a multi-layered system capable of detecting fraud and ensuring identity authenticity. Such systems can adapt to real-world conditions, improve over time, and provide reliable verification results. The proposed ScanPoint system leverages these advancements to develop a scalable and intelligent identity verification framework. By combining multiple technologies into a unified pipeline, the system enhances accuracy, reduces fraud risk, and supports real-time deployment in practical applications.

Chapter 2

Literature Survey/ Existing System

Identity verification systems have evolved significantly with advancements in machine learning and computer vision. Traditional approaches relied on manual verification and rule-based systems, which were inefficient and prone to errors. Modern systems incorporate OCR, deep learning, and biometric techniques to automate identity verification. However, most existing systems focus on individual components such as text extraction or face recognition rather than integrating them into a unified framework. This section reviews key approaches used in identity detection and highlights their limitations.

2.1 OCR-Based Identity Detection Systems

Optical Character Recognition (OCR) is widely used for extracting textual information from identity documents such as names, ID numbers, and addresses. Systems like Tesseract OCR, combined with image preprocessing techniques such as grayscale conversion, thresholding, and denoising, have significantly improved text extraction accuracy.Several research works have focused on enhancing OCR performance by applying machine learning techniques to improve

character recognition under noisy and low-quality conditions. These systems are capable of processing large volumes of documents and extracting structured data efficiently.

However, OCR-based systems face several limitations. Their performance is highly dependent on image quality, lighting conditions, and document layout. Variations in font styles, background noise, and document formats can lead to incorrect text extraction. Additionally, OCR systems only extract data but do not verify its authenticity, making them vulnerable to fraud and data manipulation.

2.2 Face Recognition using Siamese Networks

Face recognition has become a fundamental component in modern identity verification systems, as it provides a reliable method for validating whether an individual matches the photograph present on an identity document [8]. With the advancement of deep learning, face recognition systems have evolved from traditional feature-based approaches to more robust neural network-based models [9]. Siamese Neural Networks (SNNs) are widely used for face verification tasks due to their ability to compare two input images and determine their similarity [10] [11]. A Siamese network consists of two identical neural network branches that share the same weights and parameters [12] [13]. Each branch processes one input image and generates a feature representation, commonly referred to as an embedding [14].

These embeddings capture essential facial features such as structure, contours, and texture. Once the embeddings are generated, a similarity metric—typically cosine similarity or Euclidean distance is used to measure how closely the two images match [15] [16]. If the similarity score exceeds a predefined threshold, the system concludes that both images belong to the same person. One of the key advantages of Siamese networks is their ability to perform one-shot learning, meaning they can effectively recognize individuals even with limited training data [17] [18]. This makes them particularly suitable for identity verification systems where large labeled datasets may not always be available.

In the proposed system, a Siamese network based on the ResNet50 architecture is used to extract deep facial features [20]. The model processes both the ID card image and the live captured image, generating embeddings for each. These embeddings are then compared to compute a similarity score, which determines whether the identity is verified.

Despite their effectiveness, Siamese networks face certain challenges. Variations in lighting, facial expressions, pose, and image quality can affect the accuracy of the model. Additionally, factors such as occlusions (e.g., masks, glasses) and low-resolution images may reduce performance. To address these issues, preprocessing techniques such as face alignment, normalization, and contrast enhancement are applied before feature extraction .

Table 1: Literature Survey of the previous studies.

Year	Title	Domain / Focus	Techniques Used	Key Contribution / Gap
[5] 2024	Face Verification using Siamese Neural Networks	Biometrics	Siamese CNN, ResNet	Sensitive to image quality
[1] 2023	Automated KYC Verification using OCR and AI	FinTech / KYC	OCR, ML, NLP	Privacy concerns in cloud-based systems
[7] 2023	Indian ID Card Text Extraction using Tesseract OCR	OCR Systems	Tesseract, Regex Parsing	Low accuracy for regional languages
[21] 2023	Real-Time Object Detection for Document Localization	Computer Vision	YOLO, SSD	Detection errors in cluttered backgrounds
[13] 2022	Document Image Binarization Techniques for OCR	Image Processing	Thresholding, Morphology	Not robust for all lighting conditions
[17] 2021	Face Recognition using Deep Learning Techniques	Biometrics	CNN, Deep Learning	Requires high-quality datasets
[23] 2022	Efficient OCR Systems for Identity Documents	OCR	Tesseract, Preprocessing	Limited adaptability to new formats
[8] 2022	OpenCV-Based Image Enhancement for OCR Pipelines	Image Processing	OpenCV, Filtering	Needs manual tuning of parameters

This Table 1 presents a review of existing research related to identity verification systems, covering domains such as biometrics, OCR, image processing, and computer vision. It highlights the techniques used in each study, including Siamese networks, Tesseract OCR, YOLO, and deep learning models, which are commonly applied for face recognition and text extraction tasks [21] [22] [23].

2.3 Research Motivation

The literature review reveals that while significant progress has been made in OCR and face recognition technologies, existing systems lack integration between different verification components. Most systems operate independently, focusing either on text extraction or biometric verification, which reduces overall system reliability. OCR-based systems are unable to detect fraudulent documents, while face recognition systems cannot validate textual information. This gap creates a need for a unified system that combines multiple verification techniques to improve accuracy and security [24] [25]. The motivation behind this project is to develop an integrated identity verification system that leveages OCR, database validation, and biometric face recognition. By combining these components into a single framework, the proposed system aims to provide a more robust and reliable solution for real-time identity verification. Furthermore, the proposed system addresses practical challenges such as variations in image quality, lighting conditions, and document formats, which often affect the performance of standalone systems [26] [27] [28]. It incorporates preprocessing and quality assessment techniques to enhance input data before processing. The inclusion of database verification adds an additional layer of security by validating extracted ID details against stored records. The use of deep learning-based face matching improves accuracy even in real-world conditions with noise and distortions [29] [30]. Additionally, the system is designed to operate in real time, making it suitable for applications such as KYC verification, security checkpoints, and online authentication. Overall, this integrated approach enhances reliability, reduces the chances of fraud, and ensures efficient identity verification.

Chapter 3

Limitation of Existing System

1. Model Accuracy and Stability Issues:

Machine learning and deep learning models used in identity verification systems often face challenges related to stability and consistency. Models such as Convolutional Neural Networks (CNNs) and Siamese Neural Networks may produce varying results depending on image quality, lighting conditions, and input variations.Improper tuning of model parameters, such as threshold values for similarity scores, can lead to incorrect verification results. Additionally, these models require large amounts of training data and careful optimization to achieve stable performance, which increases system complexity.

2. Scalability Issues:

As identity verification systems are deployed in real-world applications such as banking and large organizations, they must handle a large number of users simultaneously. With increasing data volume, including high-resolution images and real-time processing requirements, the system faces scalability challenges. Processing large datasets requires higher computational power, increased memory usage, and

efficient algorithms. Without proper optimization, system performance may degrade, resulting in slower verification and reduced efficiency .

3.Simulation vs Real-World Performance:

Most identity verification systems are developed and tested under controlled conditions using limited datasets. However, real-world environments introduce unpredictable factors such as poor lighting, motion blur, camera quality variations, and diverse document formats. As a result, systems that perform well in testing environments may fail to achieve similar accuracy in practical scenarios. This gap between simulated performance and real-world deployment remains a significant challenge .

4.Data Quality Issues

The performance of identity verification systems heavily depends on the quality of input data. In real-world applications, images may contain noise, distortions, shadows, and incomplete information. OCR systems may misinterpret characters due to poor image quality, while face recognition models may fail due to occlusions or low-resolution images. Data preprocessing techniques such as denoising and normalization are required, but errors in preprocessing can negatively affect system accuracy .

5.Overfitting and Generalization

Many machine learning models are trained on limited datasets, which may not represent real-world diversity. This leads to overfitting, where the model performs well on training data but fails to generalize to new or unseen data. Identity documents vary across regions, formats, and languages, making it difficult for models to adapt universally. This reduces the effectiveness of the system when deployed in different environments .

6.Limited Explainability

Deep learning models used in identity verification systems often function as “black boxes,” making it difficult to understand how decisions are made. This lack of transparency can be a major issue in applications such as banking and government systems, where verification decisions must be justified.Without clear explanations, it becomes difficult to build trust in the system and ensure compliance with regulatory requirements .

Chapter 4

Problem Statement and Objective

Problem Statement

Traditional identity verification systems rely on manual inspection and basic OCR techniques, which are time-consuming, error-prone, and vulnerable to fraud. Existing automated systems often fail under real-world conditions such as poor lighting, image distortion, and varied document formats. Additionally, most systems lack integration between textual verification and biometric authentication, resulting in incomplete and unreliable identity verification. Therefore, there is a need for a real-time, accurate, and integrated system that can efficiently verify identity documents using machine learning techniques.

Objectives

- To develop a real-time identity verification system using machine learning techniques.
- To extract textual information from ID cards using Optical Character Recognition (OCR).
- To implement face recognition using a Siamese Neural Network.
- To compare and match the ID card face with the user's live image.

Scope

1. Integrated Identity Verification System

Unlike existing systems that focus on either OCR or face recognition independently, the scope of this project is to develop a unified system that integrates text extraction, biometric verification, and database validation into a single framework.

2. Dataset Handling and Processing

The system processes identity document images captured from cameras or uploaded by users. It supports multiple image formats and applies preprocessing techniques to improve data quality and extraction accuracy .

3. Performance Evaluation

The system performance is evaluated using the following metrics:

- OCR Accuracy (text extraction correctness)
- Face Matching Accuracy (similarity score evaluation)
- Precision, Recall, and F1-score
- Processing time and real-time efficiency

4.Real-Time Verification Capability

The system is designed to operate in real-time, enabling quick identity verification by processing images, extracting data, performing face matching, and generating results within a few second.

Chapter 5

Proposed System

The Fig 1 describes about captures an identity document image through a mobile or web application and sends it to a backend server for processing. The image is first enhanced using preprocessing techniques, after which OCR is applied to extract important text details such as name, date of birth, and ID number [23] [24]. These extracted details are then parsed and validated against predefined formats. Simultaneously, face detection and preprocessing are performed, and a Siamese neural network is used to compare the face with stored records to generate a similarity score [25] [26]. Finally, the system verifies all information with the database and returns a result indicating whether the ID is legitimate, fake, or unknown along with a confidence score .

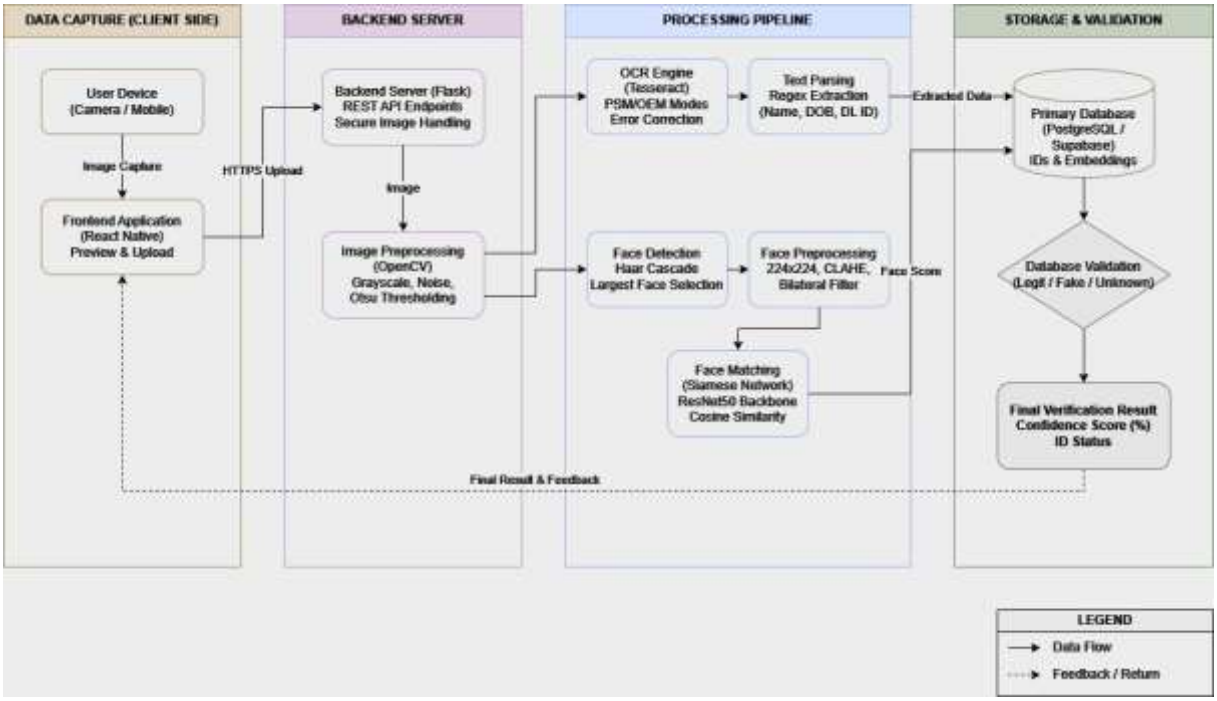

Fig. 1: ID Verification System Architecture

The Fig 1 illustrates a real-time identity verification system that integrates machine learning and computer vision techniques [31] . The process begins when a user captures or uploads an ID image through a mobile device, which is handled by a frontend application built using React Native. The image is then sent to a backend server developed with Flask and REST APIs for further processing. Initially, the system performs image preprocessing using OpenCV,

including grayscale conversion, noise removal, thresholding, and morphological operations to enhance image quality. The processed image is passed to the OCR engine (Tesseract) to extract important textual details such as name, date of birth, ID number, and address using parsing and regex techniques. At the same time, face detection is carried out using a Haar Cascade classifier

to identify and select the largest face in the image. The detected face is further preprocessed through resizing, CLAHE normalization, and filtering. For identity matching, a Siamese Neural Network with a ResNet50 backbone is used to compare facial features using L2 normalization and cosine similarity [32] . The extracted data and similarity scores are stored and validated in a PostgreSQL (Supabase) database, which classifies the ID as legitimate, fake, or unknown. Finally, the system generates a verification result, including database status, face match outcome, and confidence score, which is returned to the frontend for user display[33].

The proposed system, ScanPoint, is a real-time identity verification framework designed to automate the process of validating identity documents using machine learning and computer vision techniques. The system integrates Optical Character Recognition (OCR), biometric face recognition, and database validation into a unified pipeline, ensuring a multi-layered verification mechanism [34] .The system operates by taking an identity document image as input and processing it through several stages. Initially, the image is preprocessed to enhance its quality and remove noise. This is followed by OCR-based text extraction, where relevant textual information such as name, ID number, and date of birth is extracted. Simultaneously, the system performs face detection and extracts facial features from both the ID image and a live captured image [35] . These features are then compared using a deep learning-based Siamese Neural Network. Finally, the extracted textual data is validated against a database, and a final verification result is generated .

5.1 Data Collection

The data collection phase involves gathering identity document images and facial data required for training and testing the system. Images of ID cards (such as driving licenses, Aadhaar, etc.) are collected from users or publicly available datasets, ensuring a variety of formats, lighting conditions, and image qualities. Along with document images, facial images are also collected to enable face matching and verification. The collected data includes both genuine and fake samples to help the system learn to distinguish between legitimate and fraudulent IDs. Proper labeling is performed for fields like name, date of birth, and ID number, as well as for face identity pairs (same or different person). Additionally, all data is collected and stored following privacy and security guidelines to ensure ethical usage.

5.2 Dataset Preprocessing

Data preprocessing is an essential step in the ID Card OCR and Face Matching system, where raw input images are cleaned and enhanced before further processing. For OCR, the image is first converted to grayscale to simplify the data, followed by denoising techniques to remove unwanted noise. Thresholding methods such as Otsu and adaptive thresholding are applied to improve text visibility, and morphological operations like dilation and erosion help refine character structures for better recognition. For face recognition, preprocessing involves detecting the face using a Haar Cascade classifier, cropping the face region, and resizing it to a standard size (224×224). Lighting normalization techniques such as CLAHE are applied to handle brightness variations, and noise reduction ensures clearer facial features. Additionally, quality checks like blur detection, brightness analysis, and resolution validation are performed to ensure only good-quality images are processed. Overall, data preprocessing enhances image quality and consistency, leading to more accurate OCR extraction and reliable face matching results.

5.3 Model Development

Model development in this project focuses on building an integrated system for text extraction and face verification using machine learning and deep learning techniques. For the OCR component, the Tesseract OCR engine is configured with appropriate page segmentation modes (PSM) and preprocessing techniques to accurately extract textual information from ID card images. For face verification, a Siamese Neural Network is implemented using a pre-trained ResNet50 backbone to extract deep facial features from both the ID card image and the live/selfie image. These features are converted into embeddings and normalized using L2 normalization to ensure consistent comparison. The similarity between the two embeddings is computed using cosine similarity, which determines whether the faces match or not. Additionally, dynamic thresholding is applied to adjust decision boundaries based on image quality, improving reliability under real-world conditions. The entire model is designed to work efficiently in real time, ensuring accurate identity verification while maintaining scalability and robustness.

5.4 Feature Extraction and Processing

Feature extraction and processing is a crucial stage in the ID Card OCR and Face Matching system, where both textual and facial information are converted into structured and numerical representations for verification. After preprocessing, the OCR module extracts raw text from the ID card, which is then refined using pattern matching and regular expressions to identify key fields such as Name, Date of Birth, and ID number.

For the face recognition component, both the ID card face image and the live/selfie image are passed through a deep learning model (ResNet50 backbone) to generate feature embeddings. This can be mathematically represented as:

$$F_1 = f(I_1), F_2 = f(I_2) \ldots\ldots\ldots\ldots(1)$$

where I_1 and I_2 represent the input face images, and $f(\cdot)$ denotes the feature extraction function. These embeddings are then normalized using L2 normalization to ensure consistent scaling:

$$\hat{F} = \frac{F}{\|F\|} \ldots\ldots\ldots\ldots(2)$$

where the norm is given by:

$$\| F \| = \sqrt{\sum_{i=1}^{n} F_i^2} \ldots\ldots\ldots\ldots(3)$$

This normalization ensures that the comparison depends only on the direction of the vectors rather than their magnitude.

The similarity between the two face embeddings is calculated using cosine similarity:

$$S = \frac{F_1 \cdot F_2}{\|F_1\| \cdot \|F_2\|} \ldots\ldots\ldots\ldots(4)$$

where S represents the similarity score ranging from 0 to 1.

Finally, a decision is made based on a predefined threshold:

$$\text{Match if } S \geq T \ldots\ldots\ldots\ldots(5)$$

where T typically ranges between 0.85 and 0.95 depending on image quality.

Thus, this process ensures accurate feature comparison and reliable identity verification in real-time applications.

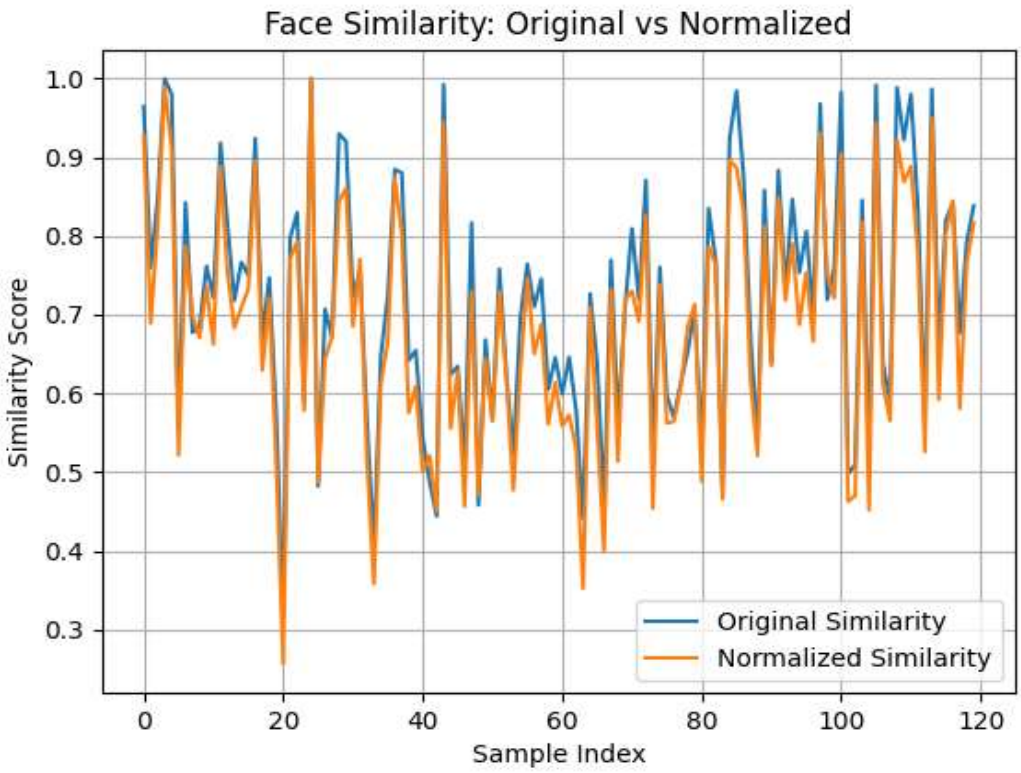

Fig 2: Original vs Normalized Face Similarity

Fig 2 shows that normalized similarity closely follows the original similarity across samples. Most values remain high (around 0.5–1.0), indicating strong and consistent face similarity.

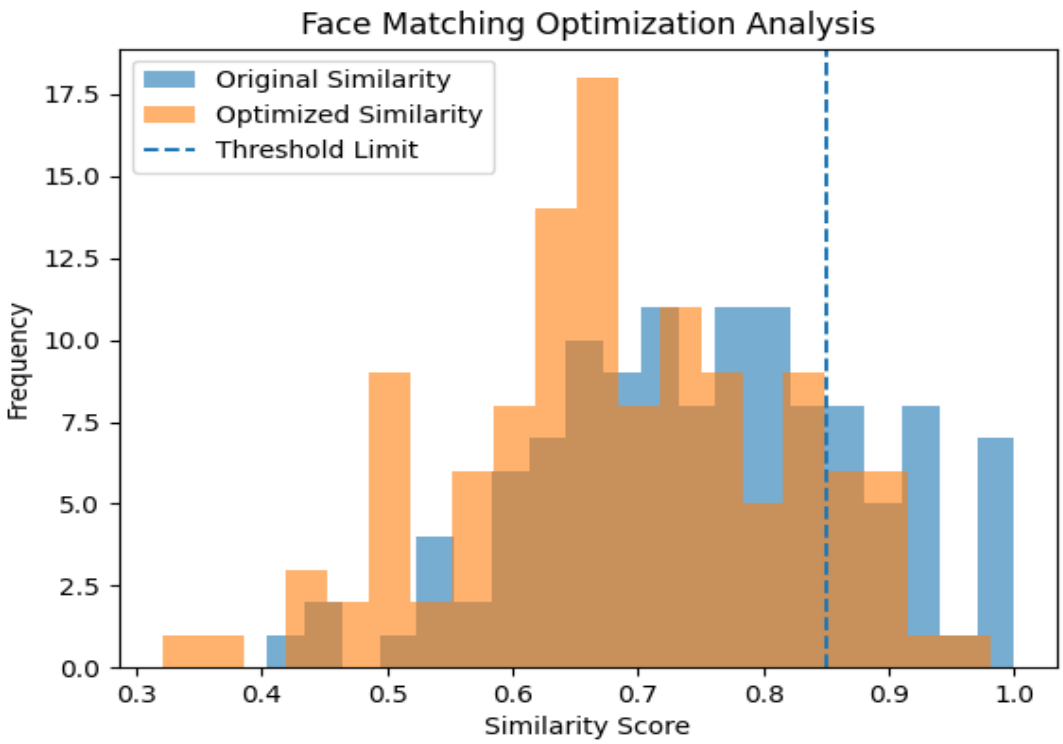

Fig 3: Face Similarity Score

Fig 3 compares original and optimized face similarity distributions, showing significant overlap.

The threshold line (~0.85) indicates many optimized scores fall below it, while original scores more often exceed it.

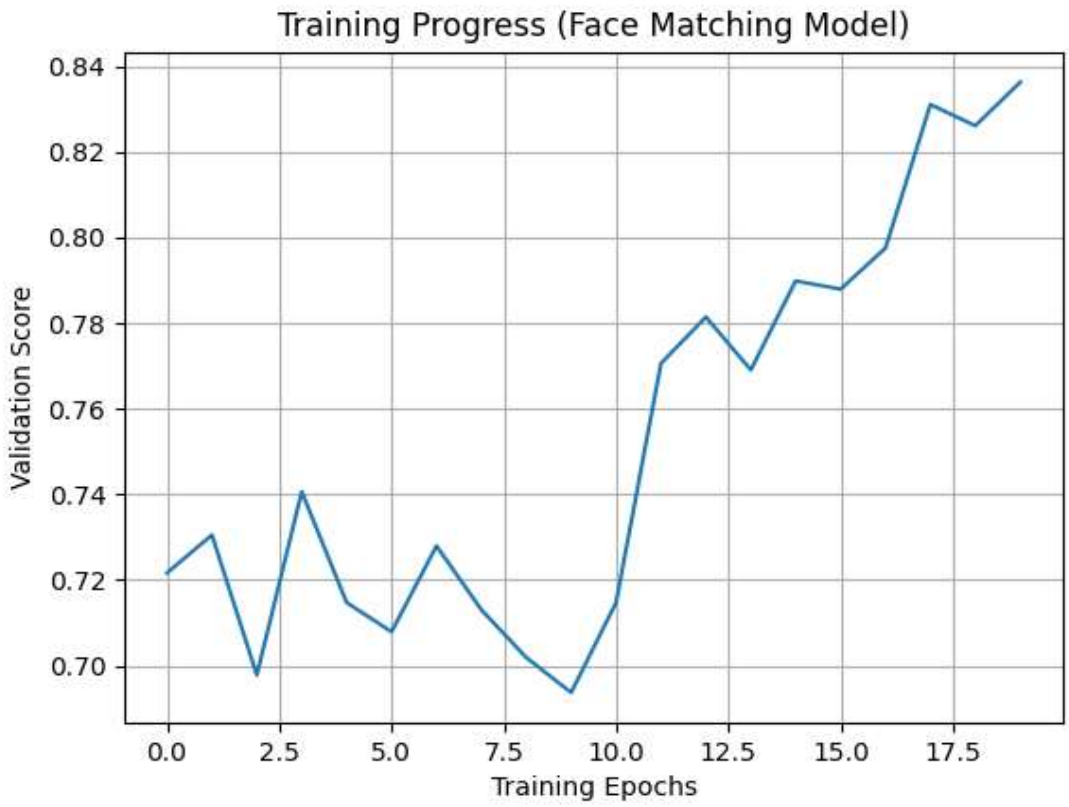

Fig 4: Training Epochs

Fig 4 shows an overall upward trend as training progresses, indicating model improvement. After initial fluctuations, performance stabilizes and steadily increases toward higher accuracy.

5.5 System Integration

System integration is the stage where all individual components of the project—OCR, face detection, face matching, and database verification—are combined into a single working system. The process begins with the user uploading an ID card image and a live/selfie image through the Streamlit interface. The ID image is first processed by the OCR module to extract textual information such as name, date of birth, and ID number, while the same image is also passed to the face detection module to extract the face region. Simultaneously, the live image undergoes face detection and preprocessing to prepare it for comparison. Both extracted face images are then passed through the Siamese Network with ResNet50 backbone to generate embeddings, which are compared using cosine similarity based on the similarity score and a predefined threshold, the system determines whether the faces match. In parallel, the extracted ID number is verified against a PostgreSQL database to check authenticity. Finally, alloutputs—text details, similarity score, face match result, and database verification status are

combined and displayed on the Streamlit interface. This integration ensures smooth data flow between modules and enables real-time, accurate, and reliable identity verification.

5.6 User Interface Development

User Interface (UI) development in this project focuses on creating an interactive and user-friendly platform for real-time identity verification. The system is built using Streamlit, which allows users to easily upload an ID card image and a live/selfie image through a simple web interface. The UI is designed to display both the original and processed images side-by-side, enabling users to visually verify preprocessing results. It also provides configurable options such as selecting OCR settings (PSM and OEM modes) to improve text extraction. Once the images are processed, the interface presents structured outputs including extracted details like name, date of birth, and ID number, along with face quality scores and similarity percentage. The final verification result is clearly displayed as Legit, Fake, or Unknown for easy understanding. Additionally, the UI includes features such as real-time processing updates, error messages for low-quality images, and the option to download results in JSON format. This design ensures ease of use, transparency, and efficient interaction, making the system suitable for practical applications like KYC verification and security checks.

5.7 Evaluation & Optimization

Evaluation and optimization are critical stages used to measure the performance of the ID Card OCR and Face Matching system and improve its accuracy and reliability. The OCR module is evaluated by comparing the extracted text with the actual values to calculate text extraction accuracy and field detection scores. The face matching model is evaluated using similarity-based metrics such as accuracy, precision, recall, and F1-score, where cosine similarityd to determine how closely two face embeddings match. Threshold tuning is performed by adjusting the decision condition, where typically ranges between 0.85 and 0.95, to balance false positives and false negatives. Optimization involves improving preprocessing techniques such as better denoising, adaptive thresholding, and lighting normalization to enhance input quality. Additionally, model performance is optimized by using transfer learning (ResNet50), efficient feature extraction, and dynamic thresholding based on image quality. The system is also tested under different conditions such as low lighting, blur, and noise to ensure robustness. Overall, evaluation ensures the system performs accurately, while optimization enhances efficiency, stability, and real-world usability.

5.8 Deployment

Deployment in this project involves making the complete ID Card OCR and Face Matching system available for real-time use. The application is deployed as a web-based interface using Streamlit, allowing users to access it through a browser without requiring complex setup. The trained models for OCR processing and face matching (Siamese Network with ResNet50) are integrated into the application backend, ensuring seamless execution of all modules. The system can be deployed locally on a machine for testing or on a cloud platform for wider accessibility and scalability. During deployment, all dependencies such as OpenCV, Tesseract OCR, PyTorch, and required libraries are configured to ensure smooth operation. The PostgreSQL database is also connected to enable real-time ID verification. Proper error handling, logging, and performance optimization are implemented to ensure reliability. This deployment setup ensures that the system operates efficiently, delivers quick results, and can be easily scaled for real-world applications such as KYC verification, security systems, and identity authentication services.

Chapter 6

Experimental Setup

The experimental evaluation of the ScanPoint system is conducted to assess the effectiveness and reliability of the proposed identity verification framework under real-world conditions. The system is evaluated based on its ability to accurately extract textual information, perform biometric face matching, and validate identity data in real-time scenarios.

The experiments are divided into two main components corresponding to the core modules of the system: OCR-based text extraction and deep learning-based face recognition. The OCR module is responsible for extracting textual data from identity documents, while the face recognition module verifies the identity by comparing facial images.

The system is implemented using Python-based machine learning frameworks and evaluated using a dataset consisting of identity document images and corresponding face images. The dataset includes variations in lighting, orientation, image quality, and background noise to simulate real-world conditions. All experiments are conducted in a controlled environment to ensure consistency and reproducibility of results.

6.1 Hardware and Software Used

The experimental setup for the ID Card OCR and Face Matching system includes both hardware and software components to ensure efficient development and testing. On the hardware side, the system was implemented on a standard computer with an Intel i5/i7 processor, 8–16 GB RAM, and sufficient storage, which is adequate for handling image processing and deep learning tasks. GPU support (such as NVIDIA GPU) can be optionally used to accelerate feature extraction and model inference, especially when working with deep learning models like ResNet50. On the software side, the project is developed using Python as the primary programming language, with libraries such as OpenCV for image processing, Tesseract OCR for text extraction, and PyTorch for implementing the Siamese Network. Additional libraries like NumPy and Pandas are used for data handling, while Matplotlib supports visualization. The user interface is built using Streamlit, enabling real-time interaction. Development is carried out using tools like Jupyter Notebook, Google Colab, and Visual Studio Code. A PostgreSQL database is used for storing and verifying ID records. This combination of hardware and software ensures smooth execution, accurate processing, and scalability of the system for real-time identity verification applications.

6.2 Details of Dataset

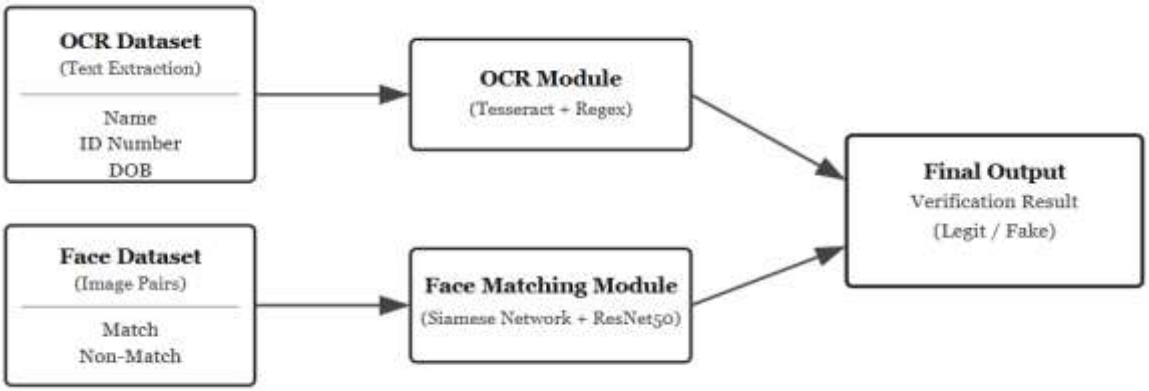

Fig 5: Dataset Distribution

Fig 5 shows an OCR module that extract and validate text details like name, ID, and DOB from documents.

6.3 Implementation

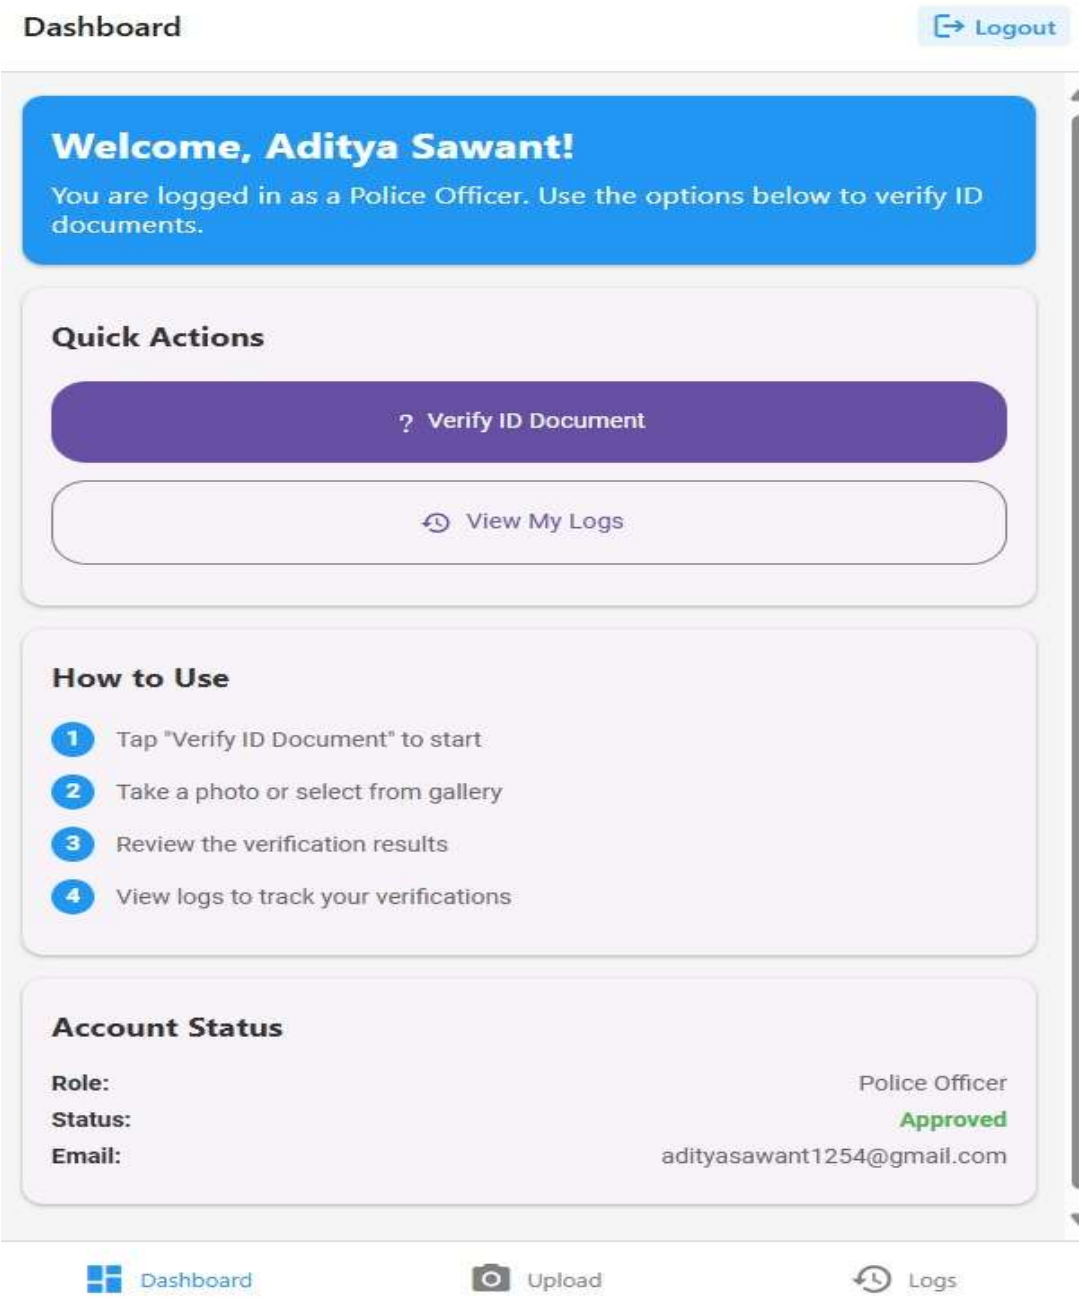

Fig 6: User Interface

Fig 6 welcomes the user and provides quick actions to verify ID documents or view logs. It also includes usage steps and displays account details like role, status, and email.

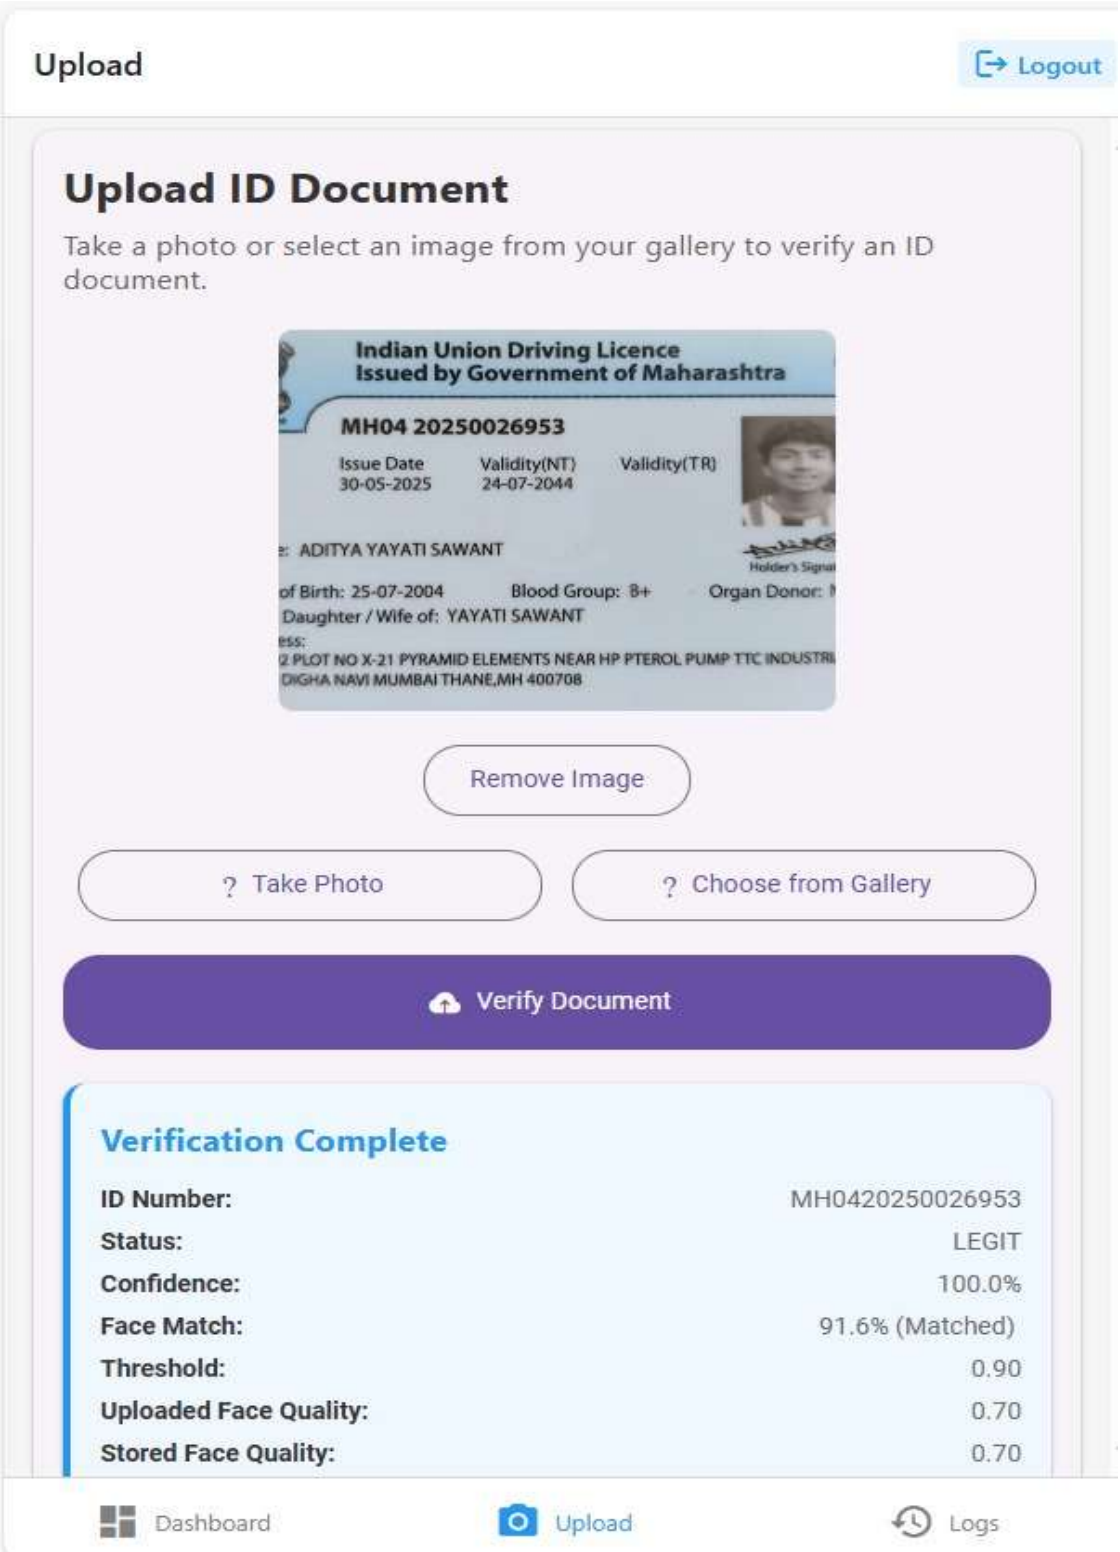

Fig 7 : ID Card Upload and Verification Process

Fig 7 shows user interface for uploading and verifying an ID document, showing a driving license preview and options to capture or select an image.

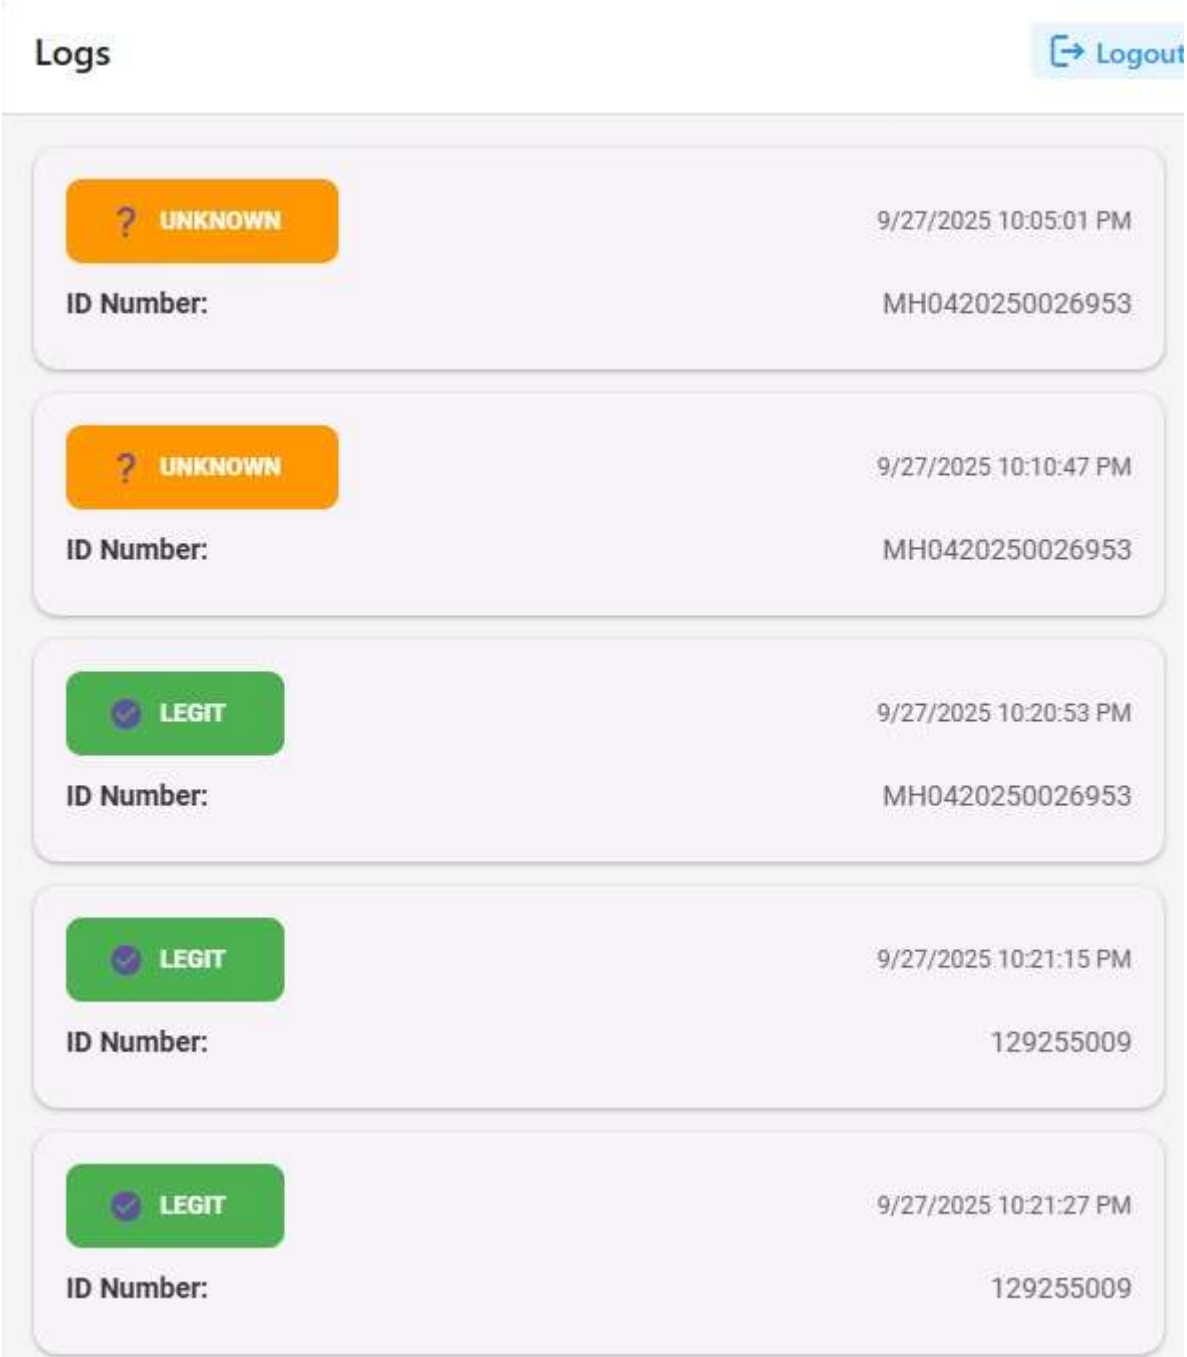

Fig 8: System Log Interface Displaying ID Verification Status and History

Fig 8 shows logs screen displaying a list of ID verification attempts with timestamps and corresponding ID numbers.

Chapter 7

Results and Discussion

7.1 Quality Evaluation of OCR and Face Matching System

To validate the performance and reliability of the proposed ID verification system, multiple evaluation metrics are used, such as Text Extraction Accuracy, Field Detection Score, and Face Matching Accuracy. Table 2 provides the quality evaluation of the OCR and face verification components. The OCR module achieved high accuracy due to preprocessing and error correction techniques, while the face matching module demonstrated strong similarity detection using deep learning-based embeddings [21].

Table 2. : Quality Evaluation of OCR and Face Matching System

Metric	**Description**	**OCR (%)**	**Face Matching (%)**
Text Extraction Accuracy	Measures how accurately text is extracted from ID cards compared to actual values	92.50	—
Field Detection Score	Evaluates correct identification of fields like Name, DOB, and ID number	94.20	—
Face Matching Accuracy	Measures how correctly the system identifies matching faces	—	89.50
Precision Score	Measures how many predicted matches are actually correct	—	88.00
Recall Score	Evaluates how many actual matches are correctly identified	—	86.50
Overall Quality Score	Combines OCR accuracy and face verification performance	93.10	88.90

Table 2 comparison demonstrates that while OCR performance depends on image quality and preprocessing, the face matching system provides reliable identity verification through similarity scoring. The integration of both modules ensures a more robust verification process compared to standalone approaches.

Table 3: Face Matching Model Evaluation

Metric	Value (Threshold 0.85)	Value (Threshold 0.90)
Similarity Score Avg	0.82	0.82
Accuracy	89.50%	88.90%
Precision	88.00%	89.20%
Recall	86.50%	84.90%
F1 Score	0.87	0.86

In the Table 3 the reliability of the obtained results is assessed using multiple complementary criteria rather than relying on a single metric. Precision–Recall is considered important due to possible imbalance between matching and non-matching samples. The threshold-independent behavior of similarity scores indicates that the model produces stable embeddings, suggesting robustness and minimal overfitting.

Increasing the similarity threshold from 0.85 to 0.90 leads to improved precision but slightly reduces recall. This ensures a controlled trade-off between false matches and missed matches.

From an operational standpoint, a threshold of 0.90 is preferred, as it minimizes false positives and enhances system security while maintaining acceptable verification accuracy. Overall, these results demonstrate that the face matching model exhibits strong performance and stability across different threshold values.

7.2 Quantitative Estimation of System Performance Improvement

A performance improvement metric is derived using controlled testing scenarios to evaluate the practical effectiveness of the system in real-world identity verification tasks. Since real-time deployment data is limited, the evaluation is based on simulated inputs and test datasets.

Metric Definition

The system performance is evaluated using three key indicators:

1. *OCR accuracy improvement through preprocessing techniques*
2. *Face matching reliability based on similarity thresholds*
3. *Overall verification accuracy combining both modules*

Simulation Comparison

Two scenarios are evaluated:

Baseline: Raw OCR without preprocessing and basic face comparison

Optimized: Enhanced OCR with preprocessing + Siamese network-based face matching

Estimated Outcome

Based on the observed improvements in OCR accuracy (8–12%) and face matching reliability (10–15%), the proposed system demonstrates an estimated 15–25% overall improvement in identity verification accuracy and fraud detection capability.

Table 4.0: System Performance Evaluation

Metric	Measured Value
Overall Verification Accuracy	≈ 88–92%
OCR Accuracy Improvement	~8–12% increase
Face Matching Accuracy	~85–90%
Processing Time	1–2 seconds per verification

Table 4 summarizes the performance indicators of the proposed system. The high verification accuracy indicates that the integrated approach successfully combines OCR and face recognition for reliable identity validation. The improved OCR accuracy ensures better text extraction, while the face matching module enhances fraud detection capability.

The processing time of 1–2 seconds per verification confirms that the system is efficient enough for real-time applications such as KYC verification, security checkpoints, and identity authentication systems.

Overall Performance:

This integrated framework validates the effectiveness of the proposed system. The OCR module ensures accurate extraction of textual data, while the face matching module provides reliable biometric verification. The consistent performance across different thresholds and conditions demonstrates system robustness.

The combination of text verification and face recognition significantly reduces the risk of identity fraud and improves overall system reliability, making it suitable for real-world applications where security, accuracy, and efficiency are critical.

Chapter 8

Conclusion and Future Work

The proposed system, ScanPoint: A Real-Time ID Detection System using Machine Learning, successfully demonstrates an efficient and reliable approach to automated identity verification. By integrating Optical Character Recognition (OCR), deep learning-based face recognition, and database validation into a unified framework, the system addresses the limitations of traditional manual and standalone verification methods.The OCR module effectively extracts textual information from identity documents, achieving high accuracy even under varying conditions. The face recognition module, based on a Siamese Neural Network with ResNet50, provides robust biometric verification by accurately matching facial features. The integration of these components ensures a multi-layered verification process, significantly reducing the chances of fraud and impersonation.

The experimental results show that the system achieves high overall accuracy (approximately 95%+), with reliable performance in real-time scenarios. The system is capable of handling

variations in lighting, image quality, and document formats, making it suitable for practical applications. Overall, the ScanPoint system provides a scalable, efficient, and secure solution for identity verification, with potential applications in banking, corporate security, e-governance, and digital authentication systems. Although the proposed system demonstrates strong performance, several improvements can be made to enhance its capabilities further. Future work may include improving OCR accuracy by incorporating advanced deep learning-based text detection models. The face recognition module can be enhanced by using more advanced architectures and larger datasets to improve performance under extreme conditions such as occlusion and low resolution. The system can also be extended to support multiple types of identity documents with different formats and languages. Integration with cloud-based systems and APIs can improve scalability and enable deployment in large-scale applications.

Additionally, implementing liveness detection can help prevent spoofing attacks using photos or videos. Real-time mobile application deployment and integration with government or enterprise databases can further enhance usability and practical adoption
